

**Correct Answer: B**

**Rationale**

Choice B is the best answer. The claim is that some concentrations of  $\text{H}_2\text{S}$  led to increased germination rates, and this choice accurately shows that seeds treated with 10 micromoles per liter of  $\text{H}_2\text{S}$  tended to germinate faster than untreated seeds.

Choice A is incorrect. This choice doesn't justify the claim. The claim compares the germination rates of seeds exposed to certain concentrations of  $\text{H}_2\text{S}$  to untreated seeds, but this choice only discusses one concentration of  $\text{H}_2\text{S}$ , so it can't support any comparison between treated and untreated groups. Choice C is incorrect. This choice misreads the graph. At 168 hours, only about 85% of seeds treated with  $\text{H}_2\text{S}$  at 500 micromoles per liter and well over 70% of untreated seeds had germinated (about 80%). Choice D is incorrect. This choice misreads the graph. At 48 hours, about 70% of seeds treated with  $\text{H}_2\text{S}$  at 10 micromoles per liter and about 50% of untreated seeds had germinated.
