

program has been a success, as the text explains, and it is reasonable to infer that an indication of the program's success would be an increase in the wild condor population compared to the captive condor population. The graph shows the wild and captive condor populations in California between 2014 and 2020. In 2014 there were slightly more than 200 wild condors in California, but by 2020 there were more than 300. Meanwhile, over the same period the captive condor population remained under 200. Thus, the biologists' claim about the program's success is supported by data from the graph showing that the number of wild California condors increased overall from 2014 to 2020 and exceeded the number of those living in captivity.

Choice A is incorrect because it does not accurately describe data from the graph. The number of captive California condors did not steadily decrease between 2014 and 2020: rather, it increased slightly during some years and decreased slightly during others, generally remaining at slightly less than 200. Choice B is incorrect. Even though the graph does show a slight decrease in both the captive and wild condor populations from 2019 to 2020, such a decrease during a particular year would not demonstrate the program's success. Choice C is incorrect because it does not accurately describe data from the graph. The difference between the number of captive and wild California condors did not remain relatively steady between 2014 and 2017. While the number of captive condors remained roughly the same during that period, the number of wild condors increased, so the difference between the number of captive and wild condors increased as well.
